(57) **ABSTRACT**

A server includes a communications adapter; a controller and a datastore. The controller receives a first user input via a user interface to associate at least one image attribute with a contact. Thereby, responsive to receiving an image from an electronic apparatus, the controller automatically processes the image to identify at least one feature of the image that corresponds to the image attribute, and associates the image with the contact based on the image attribute; and communicates the image to the contact via the communications adapter. The datastore is suitable for storing digital information, and is communicatively coupled to the controller.

AUTOMATED COMMUNICATION USING IMAGE CAPTURE

RELATED APPLICATIONS

This a continuation of application Ser. No. 11/537,118 filed Sep. 29, 2006, and titled "AUTOMATED COMMUNICATION USING IMAGE CAPTURE". These applications are commonly owned by Motorola Mobility, Inc., and priority is taken therefrom from the earlier filed application. The entire contents of the earlier filed application are incorporated herein by reference.

CHANGE IN POWER OF ATTORNEY

The power of attorney has changed from the parent application Ser. No. 11/537,118. On Feb. 9, 2011 the USPTO accepted power of attorney for Customer No.: 20280, MOTOROLA MOBILITY, INC. and revoked the previous power of attorney for Customer No.: 44984, CUENOT, FORSYTHE & KIM.

FIELD OF THE INVENTION

The present invention generally relates to mobile communication devices and, more particularly, to such devices that include image capture features.

BACKGROUND OF THE INVENTION

Mobile stations have become a part of modern life in most parts of the world. People now can conveniently communicate from virtually anywhere within an industrialized country, and while performing any of a number of activities. For instance, mobile station users can communicate while strolling through a park, exercising at the gym or commuting to work.

Notwithstanding the convenience mobile stations provide, they also can be a source of irritation to some users, such as those who receive a call at an inopportune time or who are not able to break free from a lengthy conversation. Accordingly, there continues to be a need for mobile station features that improve the user experience.

SUMMARY OF THE INVENTION

A server includes a communications adapter; a controller and a datastore. The controller receives a first user input via a user interface to associate at least one image attribute with a contact. Thereby, responsive to receiving an image from an electronic apparatus, the controller automatically processes the image to identify at least one feature of the image that corresponds to the image attribute, and associates the image with the contact based on the image attribute; and communicates the image to the contact via the communications adapter. The datastore is suitable for storing digital information, and is communicatively coupled to the controller.

BRIEF DESCRIPTION OF THE DRAWINGS

Preferred embodiments of the present invention will be described below in more detail, with reference to the accompanying drawings, in which:

FIG. 1 depicts a communications system that is useful for understanding the present invention;

FIG. 2 depicts a block diagram of a communication device that is useful for understanding the present invention;

2

FIG. 3 depicts a block diagram of a server that is useful for understanding the present invention;

FIG. 4 depicts a contact list that is useful for understanding the present invention.

5 FIG. 5 is a flowchart that is useful for understanding the present invention; and

FIG. 6 is another flowchart that is useful for understanding the present invention.

DETAILED DESCRIPTION

10 While the specification concludes with claims defining features of the invention that are regarded as novel, it is believed that the invention will be better understood from a consideration of the description in conjunction with the drawings. As required, detailed embodiments of the present invention are disclosed herein; however, it is to be understood that the disclosed embodiments are merely exemplary of the invention, which can be embodied in various forms. Therefore, specific structural and functional details disclosed herein are not to be interpreted as limiting, but merely as a basis for the claims and as a representative basis for teaching one skilled in the art to variously employ the present invention in virtually any appropriately detailed structure. Further, the terms and phrases used herein are not intended to be limiting but rather to provide an understandable description of the invention.

15 The present invention relates to a method and a system for quickly and efficiently communicating messages to one or more contacts. In particular, a user of a communication device can associate image attributes with the contacts. Further, messages also can be associated with the contacts and/or with the image attributes. When the communication device receives an image containing a feature that correlates to a known image attribute, the image and corresponding message can be automatically sent to the contact(s) with whom the image attribute is associated. For example, the user can associate image attributes corresponding to flowers with a contact, and can associate the message "thinking of you" with the image attributes. In response to the communication device capturing an image of a flower that has features that correlate to the image attributes, the communication device can automatically associate the message with the captured image and communicate the captured image and message to the contact. In this manner, a meaningful multimedia message can be communicated to a contact merely by the act of taking a picture.

20 FIG. 1 depicts a communications system **100** that is useful for understanding the present invention. The communications system **100** can include a communications network **105**, which can comprise, for example, the Internet, the World Wide Web, a wide area network (WAN), a local area network (LAN), a cellular communications network, a dispatch communications network, an interconnect communications network, a public switched telephone network (PSTN), and/or any other networks or systems over which communication signals can be propagated. In that regard, the communications network can include wired and/or wireless communication links.

25 The communications system **100** also can include a communication device **110** and a communication device **115**. The communication device **110** can be a mobile station, such as a mobile computer, a personal digital assistant (PDA) or a mobile telephone, a camera that includes communications functionality, or any other electronic apparatus that may be used to send a communication **120** containing an image **125** via the communications network **105**. The communication

120 can be propagated via wireless and/or wireless communication links. Similarly, the communication device **115** can be a mobile station, a computer, a set top box, an image display device, or any other electronic apparatus that may be used to receive the communication **120**. The communication device **115** can be communicatively linked to the communications network **105** and can receive the communication **120** via wired and/or wireless communication links.

In operation, the communication device **110** can receive the image **125**. For example, in response to a user input, the communication device **110** can capture an image of an object **130**, such as a flower. The communication device **110** then can process the received image **125** to identify features which may correlate to image attributes associated with one or more contacts.

The communication device **110** also can identify one or more messages associated with the image attributes and/or the contacts. Such messages can comprise text, audio, still images and/or video. In one arrangement, the audio that is provided in the message can be pre-recorded. For instance, if the received image **125** contains features associated with a motorcycle, the audio can include the sound of a motorcycle. In another arrangement, the audio can be recorded when the image **125** is received. For example, before, during or after capturing an image with the communication device, the communication device **110** can prompt the user to provide an audio input, such as a spoken utterance. An ambient sound detected by the communication device also can be recorded.

The communication device **110** then can send the communication **120**, which may include the image **125** and a corresponding message, to the contact. For instance, the communication device **110** can forward the communication **120** to the communication device **115**, which may be associated with the contact, and/or to other communication devices associated with other contacts with whom correlating image attributes are associated. The communication **120** can be initiated in response to a user input, automatically initiated in response to the image being received by the communication device **110** while the communication device **110** is in a particular image communication mode, or initiated in any other suitable manner.

In another arrangement, in response to receiving the image **125**, the communication device **110** can automatically communicate the image **125** to a server **135**, and the server **135** can process the image to identify image features which may correlate to the image attributes associated with the contact(s). The server **135** also can identify the messages associated with the image attributes and/or the contact(s). The server then can forward the image **125** and the corresponding message(s) to the contact(s) in the communication **120**. The server **135** can be a network server, a web server, a mobile switching center (MSC), a basestation controller (BSC), or any other device suitable for implementing the server processes described herein.

Image processing profiles can be established on the communication device **110** and/or the server **135**. In one arrangement, one or more messages can be associated with image attributes and/or contacts which prompt the contacts to provide feedback after receiving the image **125**. For example, a shopping profile can be established. This profile can associate image attributes correlating to images of clothing with a plurality of contacts. The associated message can, for instance, prompt contacts who are friends of the user to provide their opinions of the clothing. Opinions submitted by the contacts can be received as textual responses, as icons which indicate approval, disapproval or indifference, as still images or video, or in any other suitable manner. A second message

can ask a parent of the user for his/her approval for purchase of the clothing. Again, such response can be received in any suitable manner. In one arrangement, the communication **120** also can indicate a present location of the communication device **110**. The location can be determined, for instance, using a global positioning system (GPS) (e.g. a GPS receiver), a local positioning system, or in any other suitable manner. In one aspect of the invention, the local positioning system can include a transponder that identifies a store in which the communication device **110** is located, and such information can be included in the communication **120**.

In another example, features of the image **125** can be analyzed to determine whether certain authorities should be contacted. For example, if the image features correspond to attributes which indicate an emergency, for instance a vehicle is on fire, the communication **120** can be propagated to emergency responders, such as a fire department and/or a police department. The message that is associated with the image **125** in the communication **120** can indicate a location of the present emergency. The location can be determined using a GPS receiver, a local positioning system or in any other suitable manner. In response to the communication **120**, such authorities can communicate to the communication device **110** instructions for dealing with the present emergency and/or other information, such as present location and estimated time of arrival of emergency responders.

In one arrangement, the present location information can be provided as a map which includes the location of the emergency and the present location of the emergency responders. In another arrangement, a name can be associated with the location information. The name can be a name of a place, such as a store or a shopping center, or a name of a geographic region, such as a neighborhood, village, town, city, etc. Further, a link can be provided to the communication device **110** which enables the communication device **110** to receive updates pertaining to the emergency responders. The link can be, for example, a uniform resource identifier (URI) associated with a portal that provides such updates.

FIG. 2 depicts a block diagram of the communication device **110** that is useful for understanding the present invention. The communication device **110** can include a controller **205**. The controller **205** can comprise, for example, a central processing unit (CPU), a digital signal processor (DSP), an application specific integrated circuit (ASIC), a programmable logic device (PLD), a plurality of discrete components that cooperate to process data, and/or any other suitable processing device.

The communication device **110** also can include a communications adapter **210**. The communications adapter **210** can be any network adapter suitable for communicating via the communications network. For example, the network adapter can include a transceiver that communicates data via wireless communications and/or a communications port or network adapter that communicates via wired communications.

The communication device **110** also can include an image capture device **215**. The image capture device **215** can include an image sensor, such as a charge-coupled device (CCD), a complementary metal oxide semiconductor (CMOS) image sensor, or any other image sensor suitable for detecting images. The image capture device **215** also can include an image processor that processes the images detected by the image sensor and generates image data. Image capture devices are well known to those skilled in the art.

A user interface **220** also may be provided with the communication device **110**. The user interface **220** can include a keypad, a display, buttons, sensors, input and output audio

5

transducers, and/or any other devices which may receive user inputs or present information to a user.

The communication device **110** further can include a positioning system **225**. The positioning system **225** can include a GPS receiver, a receiver that detects local positioning signals, a receiver that detects a local transponder, and/or any other suitable position identification system or device.

Further, the communication device **110** can include a datastore **230**. The datastore **230** can include one or more storage devices, each of which can include a magnetic storage medium, an electronic storage medium, an optical storage medium, a magneto-optical storage medium, and/or any other storage medium suitable for storing digital information. In one arrangement, the datastore **230** can be integrated into the controller **205**.

An image messaging application **235** can be contained on the datastore **230**. The image messaging application **235** can be executed by the controller **205** to implement the methods and processes described herein. An image database **240** also can be stored on the datastore **230**. The image database **240** can associate each of a plurality of image features with unique attributes. Further, the image database **240** also can associate messages with the unique attributes. For example, the message "thinking of you" can be associated with attributes corresponding to image features of flowers. As noted, the messages also can comprise audio. For instance, a message which includes the sound of chirping birds can be associated with the attributes that correspond to the image features of flowers.

The data store **230** also can include a contact list **245**. In addition to providing names of contacts, the contact list **245** can associate image attributes contained in the image database **240** with one or more of the contacts. For example, image attributes associated with a particular type of flower can be associated with a first contact, and image attributes associated with a motorcycle can be associated with a second contact. Messages also can be associated with the contacts.

At runtime, the image messaging application **235** can receive the image **125** from the image capture device **215** or the communications adapter **210**. The image messaging application **235** can process the image **125** to identify one or more features of the image **125** that correlate to image attributes that are contained in the image database **240** and which are associated with contacts in the contact list **245**.

To identify the features of the image, the messaging application **235** can process the image **125** using known image recognition techniques. For example, a discriminator algorithm can process the image **125** to identify objects in the image **125**, and decomposition can be performed on such objects to identify different quantifiable salient attributes. The image decomposition can include radiometric correction, segmentation and/or segment group generation. For each generated segment group, additional processing steps can be performed, for instance bounding box generation, geometric normalization, wavelet decomposition, color cube decomposition, shape decomposition and/or low-resolution grayscale image generation. Such techniques are described in U.S. Patent Application Publication No. US 2002/0090132 A1 filed Nov. 5, 2001, which is herein incorporated by reference in its entirety. In the case of conflict, the present specification, including definitions, will control.

After a feature contained in the image **125** has been identified that correlates to an image attribute associated with a contact, the image messaging application **235** can initiate the communication **120** containing the image **125**. The communication **120** can be forwarded by the communications adapter **210** to the contact or contacts with whom the image attribute is associated. In addition, one or more messages can

6

be included in the communication **120**. For example, a message associated with the image attribute and/or a message that has been associated with the contact can be included in the communication **120**. A location of the communication device **110** can be determined by the positioning system **225** and also included in the communication **120**.

FIG. **3** depicts a block diagram of the server **135** that is useful for understanding the present invention. As noted, the image **125** can be communicated to the server **135** from the communication device and the server can process the image **125** to identify features which correspond with the image attributes. The server **135** then can generate the communication **120** which includes the image **125** and the corresponding message(s). Location information, if applicable, also can be communicated to the server **135** from the communication device. The server **135** also can include such location information in the communication **120**.

In the arrangement in which the server **135** generates the communication **120**, the server **135** can include the controller **205** (or processor), the communications adapter **210** and the datastore **230**. Of course, the imaging messaging application **235**, the image database **240** and the contact list **245** can be contained on the datastore **230**, or contained on another datastore accessible to the server **135**.

FIG. **4** depicts a contact list **400** that is useful for understanding the present invention. The contact list **400** can include names **405** of contacts or groups, names **410** of attributes that can be associated with the contacts or groups, and messages **415** that can be associated with the contacts or groups. The names **405** can be entered in to the contact list **400** in any suitable manner, for example, using a keyboard or keypad, buttons, or by processing a spoken utterance using voice recognition software. Similarly, the messages **415** can be entered into the contact list **400** and associated with the contacts or groups **405** in any suitable manner.

The attribute names **410** can be selected from a menu of defined attributes. The attribute names **410** can be selected, for example, using a drop-down menu or in any other suitable manner. When an attribute name **410** is selected, image attributes corresponding to the name **410** can be identified in a data table or a data file and associated with the name **405** of a contact or group. For example, if the name **410** of an image attribute that is selected for Jane is "Rose," image attributes of a rose can be associated with Jane. Similarly, if the name **410** of the image attribute that is selected for Fred is "Motorcycle," image attributes of a motorcycle can be associated with Fred, and so on.

In addition to the fields that are shown in the contact list **400**, a plurality of other fields also can be included in the contact list **400**. For example, the contact list can include telephone numbers, physical addresses, e-mail addresses, and/or any other desired information.

FIG. **5** is a flowchart presenting a method **500** that is useful for understanding a process of associating image attributes to one or more contacts. Beginning at step **505**, one or more image attributes can be selected. For example, a list of known image attributes can be presented on a communication device, and a user can select from the known image attributes. Such image attributes can be retrieved from a suitable database and/or data file in which they are stored. The database and/or data file can be contained on the communication device, or on a server to which the communication device is communicatively linked.

Proceeding to step **510**, the selected image attributes can be associated with one or more contacts. For instance, the selected image attributes can be associated with a single contact or a plurality of contacts identified in a contact group.

In such an arrangement, associating the image attributes with the contact group can effectuate association of the image attributes with each of the members of the contact group. Contact information for individual members can be individually edited to un-associate or re-associate such contacts with the image attributes.

Continuing to step **515**, one or more messages can be associated with the selected image attributes and/or the contacts. For example, the message "thinking of you" can be associated with an image attribute corresponding to features of a flower and to a particular contact. Alternatively, the message can be associated either with the image attributes or with the contact.

FIG. 6 is a flowchart presenting a method **600** that is useful for understanding a process of sending a communication, which includes a captured image and an associated message, to one or more contacts. At step **605**, a communication device can enter into an image messaging mode. For example, a user can select the image messaging mode from a menu of available device operation modes. At step **610**, an image can be received by the communication device. The image can be captured by an image capture device operatively connected to, or incorporated in, the communication device. Alternatively, the image can be received via a communications adapter. For instance, the image can be downloaded from a web site or received from another communication device.

Proceeding to step **615**, the image can be automatically processed to identify features of the image that correspond to known image attributes. As noted, such processing is known to the skilled artisan. Continuing to step **620**, one or more contacts with whom the image attributes have been associated can be selected. In addition, at step **625**, one or more messages associated with the image attributes and/or the selected contacts can be selected. As noted, such messages can comprise text, audio, still images and/or video. At step **630**, a communication that includes the image and the selected message(s) can be automatically sent to the selected contact(s). In an arrangement in which location information for the communication device is available, such location information also can be included in the communication.

The present invention can be realized in hardware, software, or a combination of hardware and software. The present invention can be realized in a centralized fashion in one processing system or in a distributed fashion where different elements are spread across several interconnected processing systems. Any kind of processing system or other apparatus adapted for carrying out the methods described herein is suited. A typical combination of hardware and software can be a processing system with an application that, when being loaded and executed, controls the processing system such that it carries out the methods described herein. The present invention also can be embedded in an application product, which comprises all the features enabling the implementation of the methods described herein, and which when loaded in a processing system is able to carry out these methods.

The terms "computer program," "software," "application," variants and/or combinations thereof, in the present context, mean any expression, in any language, code or notation, of a set of instructions intended to cause a system having an information processing capability to perform a particular function either directly or after either or both of the following: a) conversion to another language, code or notation; b) reproduction in a different material form. For example, an application can include, but is not limited to, a subroutine, a function, a procedure, an object method, an object implementation, an executable application, an applet, a servlet, a source code, an object code, a shared library/dynamic load library and/or other sequence of instructions designed for execution on a processing system.

The terms "a" and "an," as used herein, are defined as one or more than one. The term "plurality," as used herein, is defined as two or more than two. The term "another," as used herein, is defined as at least a second or more. The terms "including" and/or "having," as used herein, are defined as comprising (i.e., open language).

This invention can be embodied in other forms without departing from the spirit or essential attributes thereof. Accordingly, reference should be made to the following claims, rather than to the foregoing specification, as indicating the scope of the invention.

We claim:

1. A server, comprising:
a communications adapter; and
a controller that:
receives a first user input via a user interface to associate at least one image attribute with a contact;
responsive to receiving an image from an electronic apparatus, automatically processes the image to identify at least one feature of the image that corresponds to the image attribute, and associates the image with the contact based on the image attribute; and communicates the image to the contact via the communications adapter; and
a datastore, suitable for storing digital information, and communicatively coupled to the controller.
2. The server claimed in claim 1, wherein the datastore comprises an image messaging application.
3. The server claimed in claim 2, wherein the image messaging application comprises audio messages.
4. The server claimed in claim 2, wherein the image messaging application comprises text messages.
5. The server claimed in claim 2, wherein the image messaging application comprises image decomposition processing.
6. The server claimed in claim 1, wherein the electronic apparatus is linked to a communication network.
7. The server claimed in claim 6, wherein the electronic apparatus is capable of sending a communication containing an image via the communication network.

* * * * *
